Introduction

Most patients undergoing lung transplantation present to the operating room with some degree of RV dysfunction. Evidence suggests that improvement in RV function and remodelling do occur months after lung transplant. Little is known on intraoperative changes in RV function. RV strain by speckle tracking is a new echocardiographic

parameter that allows precise determination of RV function and correlates with long-term outcomes in patients with pulmonary hypertension.

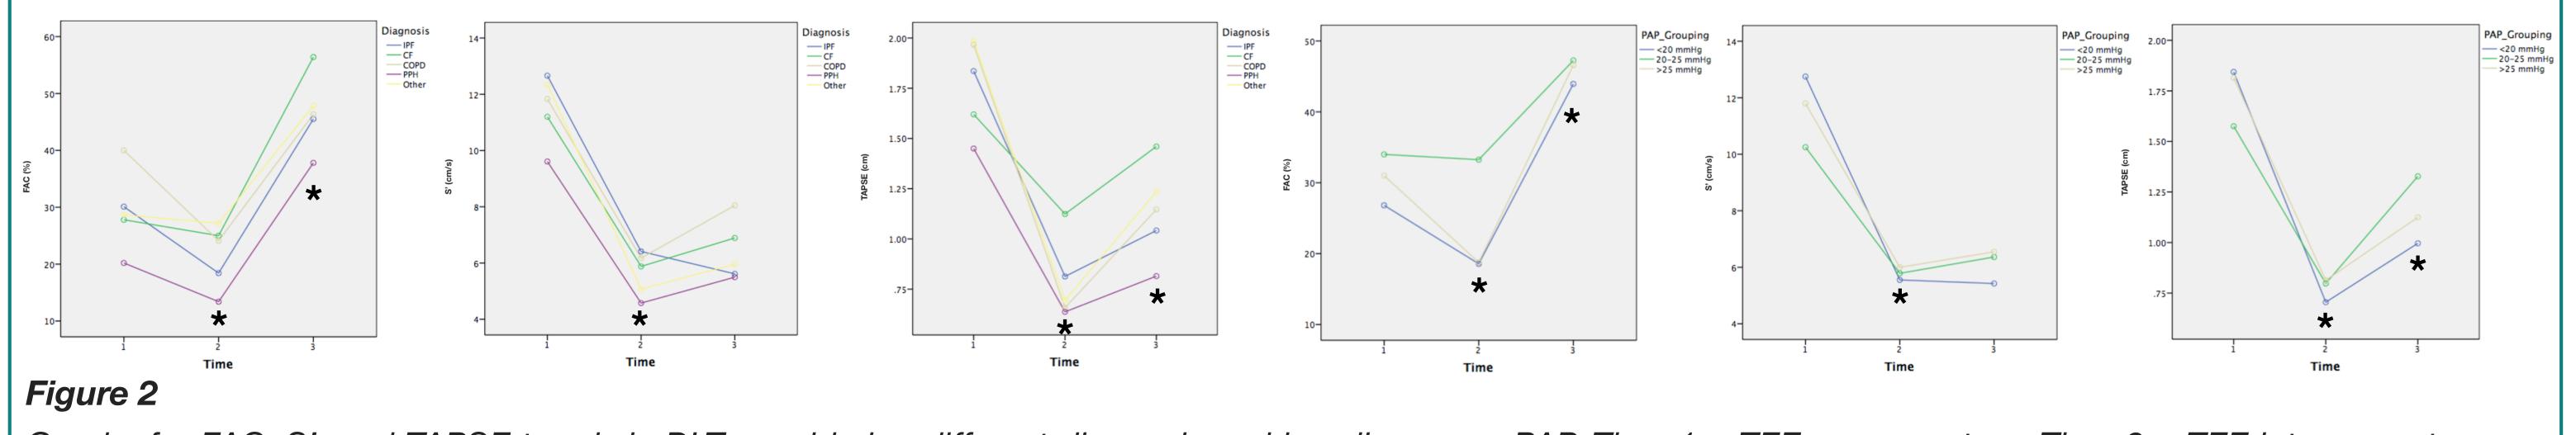

Methods

After Institutional Research Ethic Board Approval we reviewed patient who underwent single and double lung transplantation at Toronto General Hospital between July 2014 and August 2017 and had an intraoperative transesophageal echocardiography (TEE). Midesophageal RV images were analysed using Echolnsight® software to assess RV Global Longitudinal Strain (GLS), Fractional Area Change (FAC), Tricuspid Annular Plane Systolic Excursion (TAPSE) and S' at baseline and after lung transplant (Figure 1).

Results

156 double (DLT) and 28 single lung transplants (SLT) recipients were included. After DLT, we found a statistically significant improvement of all RV function parameters. After SLT a similar trend was observed with the exception of a worsening of S' and TAPSE measurements. In DLT, the improvement of all RV function parameters was irrespective of underlying lung pathology and baseline mean pulmonary artery pressure (PAP) (Figure 2).

Graphs for FAC, S', and TAPSE trends in DLT considering different diagnosis and baseline mean PAP. Time 1 = TEE pre-operatory; Time 2 = TEE intra-operatory pretransplant; Time 3 = TEE intra-operatory post-transplant; CF = Cystic Fibrosis; COPD = Chronic Obstructive Pulmonary Disease; IPF = Idiopathic Pulmonary Fibrosis; PPH = Primary pulmonary Hypertension. r = p < 0.05 within groups

Conclusion

RV GLS, FAC, S' and TAPSE demonstrated a statistically significant improvement in RV function immediately after lung transplant regardless of indication and pulmonary arterial pressure. A lack of improvement of some traditional parameters RV function was noticed for SLT recipients. Further analysis is needed to determine the impact of RV function on short and long term.
